1.

Which of the following is true for our dynamic programming algorithm for computing a maximum-weight independent set of a path graph? (Assume there are no ties.)

The algorithm always selects the maximum-weight vertex.

If a vertex is excluded from the optimal solution of a subproblem, then it is excluded from the optimal solutions of all bigger subproblems.

Incorrect Response

How many different smaller subproblems are used to compute the optimal solution of a subproblem?

As long as the input graph has at least two vertices, the algorithm never selects the minimum-weight vertex.

If a vertex is excluded from the optimal solution of two consecutive subproblems, then it is excluded from the optimal solutions of all bigger subproblems.

2.

Consider a variation of the Knapsack problem where we have two knapsacks, with integer capacities W_1 and W_2 . As usual, we are given n items with positive values and positive integer weights. We want to pick subsets S_1, S_2 with maximum total value (i.e., $\sum_{i \in S_1} v_i + \sum_{i \in S_2} v_i$) such that the total weights of S_1 and S_2 are at most W_1 and W_2 , respectively. Assume that every item fits in either knapsack (i.e., $w_i \leq \min\{W_1, W_2\}$ for every item i). Consider the following two algorithmic approaches. (1) Use the algorithm from lecture to pick a max-value feasible solution S_1 for the first knapsack, and then run it again on the remaining items to pick a max-value feasible solution S_2 for the second knapsack. (2) Use the algorithm from lecture to pick a max-value feasible solution for a knapsack with capacity $W_1 + W_2$, and then split the chosen items into two sets S_1, S_2 that have size at most W_1 and W_2 , respectively. Which of the following statements is true?

Algorithm (1) is guaranteed to produce an optimal feasible solution to the original problem provided $W_1 = W_2$.

Algorithm (1) is guaranteed to produce an optimal feasible solution to the original problem but algorithm (2) is not.

Algorithm (2) is guaranteed to produce an optimal feasible solution to the original problem but algorithm (1) is not.

Neither algorithm is guaranteed to produce an optimal feasible solution to the original problem.

Correct Response

Indeed. Can you devise from scratch a dynamic programming algorithm that correctly solves the problem?

3.

Recall our dynamic programming algorithm for computing the maximum-weight independent set of a path graph. Consider the following proposed extension to more general graphs. Consider an undirected graph with positive vertex weights. For a vertex v , obtain the graph $G'(v)$ by deleting v and its incident edges from G , and obtain the graph $G''(v)$ from G by deleting v , its neighbors, and all of the corresponding incident edges from G . Let $OPT(H)$ denote the value of a maximum-weight independent set of a graph H . Consider the formula $OPT(G) = \max\{OPT(G'(v)), w_v + OPT(G''(v))\}$, where v is an arbitrary vertex of G of weight w_v . Which of the following statements is true?

- ☐ The formula is correct in path graphs but is not always correct in trees.
- ☐ The formula is always correct in general graphs, and it leads to an efficient dynamic programming algorithm.
- ☐ The formula is always correct in trees, but does not lead to an efficient dynamic programming algorithm.
- ☒ The formula is always correct in trees, and it leads to an efficient dynamic programming algorithm.

Correct Response

Indeed. What running time can you get?

points

4.

Recall the dynamic programming algorithms from lecture for the Knapsack and sequence alignment problems. Both fill in a two-dimensional table using a double-for loop. Suppose we reverse the order of the two for loops. (I.e., cut and paste the second for loop in front of the first for loop, without otherwise changing the text in any way.) Are the resulting algorithms still well defined and correct?

- ☐ The sequence alignment algorithm remains well defined and correct after reversing the order of the for loops, but the Knapsack algorithm does not.
- ☐ Neither algorithm remains well defined and correct after reversing the order of the for loops.
- ☐

The Knapsack algorithm remains well defined and correct after reversing the order of the for loops, but the sequence alignment algorithm does not.

Both algorithms remain well defined and correct after reversing the order of the for loops.

Correct Response

The necessary subproblem solutions are still available for constant-time lookup.

5.

Consider an instance of the optimal binary search tree problem with 7 keys (say 1,2,3,4,5,6,7 in sorted order) and frequencies

$w_1 = .05$, $w_2 = .4$, $w_3 = .08$, $w_4 = .04$, $w_5 = .1$, $w_6 = .1$, $w_7 = .23$. What is the minimum-possible average search time of a binary search tree with these keys?
